

4.401/4.464 Environmental Technologies in Buildings

Old weather station on the roof of the MIT Green Building

Christoph Reinhart

1
L03 Understanding Climate – Solar Radiation

Today's Learning Objectives

To understand:

- How local **microclimate** is measured.
- The amount of solar radiation worldwide.

Measuring Climate

*What do you think we should
measure?*

Climate Data

Dry Bulb Temperature [$^{\circ}\text{C}$]

Relative Humidity [%]

Direct Solar Radiation [W/m^2]

Diffuse Horizontal Solar Radiation [W/m^2]

Wind speed [km/h]

Wind direction [Degree]

Cloud Cover [%]

Rainfall [mm]

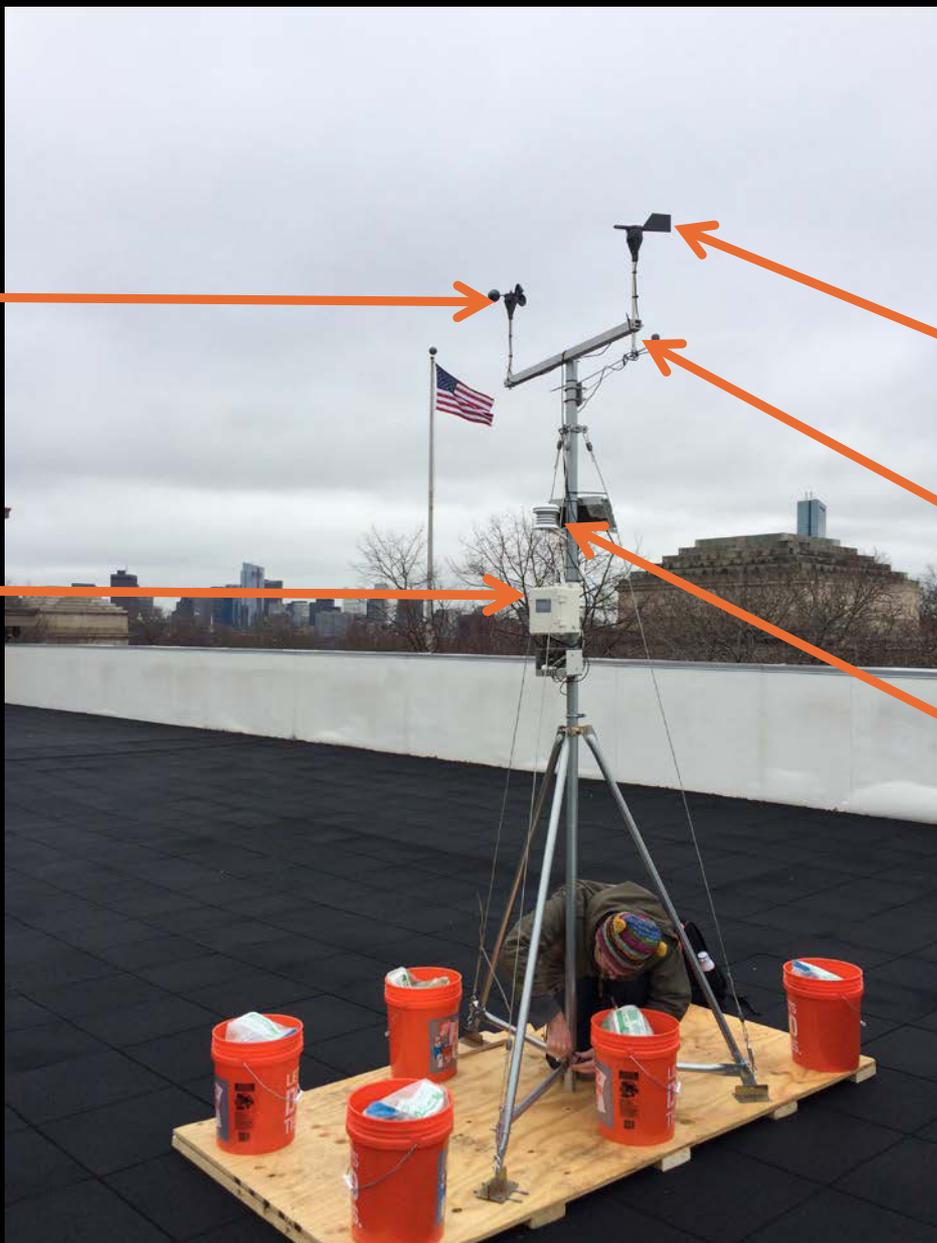

*You should start developing
a feeling for typical inside
and outside levels.*

Weather Station

MIT Building 1

Wind Speed
(cup anemometer)

Data Logger

Wind Direction (vane)

Solar Radiation

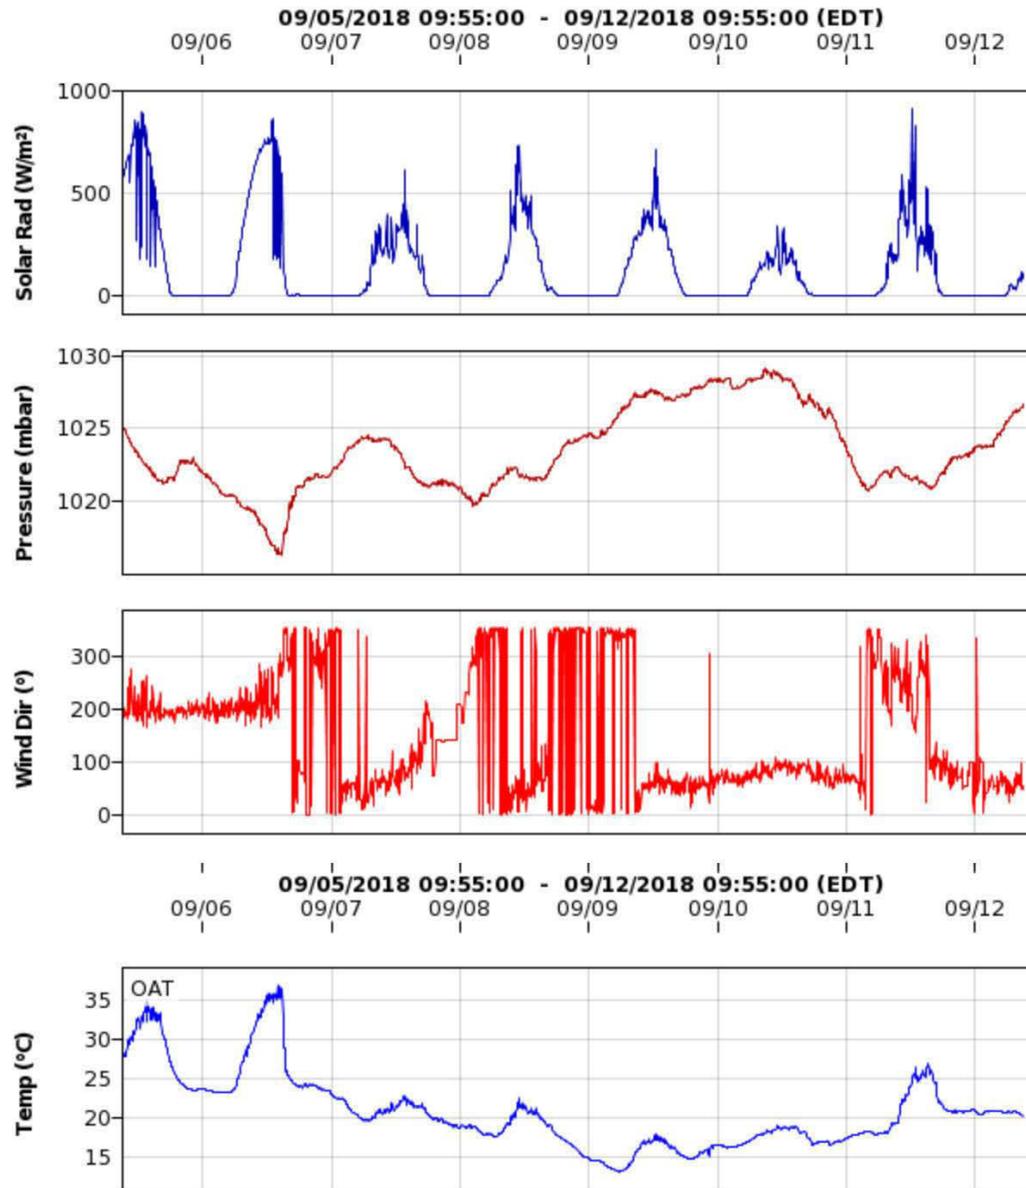

Temperature & Relative Humidity

Hardware Costs ~\$2000 (2008)

(Weather Station Starter Kit \$1214; Tripod Kit \$245; Hobo Software \$99; 2 PC cables \$18; Solar Radiation Sensor \$199; Light Sensor Bracket \$25; Light Sensor Level \$30)

MIT Building 1 Weather Station

Climate Files

A Typical Meteorological Year (TMY) is defined as a set of real measured hourly values for dry temperature, for global, diffuse, and direct normal solar radiation, and for wind velocity. The data are in true sequence within each month. The most important input variables are:

Dry Bulb Temperature [$^{\circ}\text{C}$]

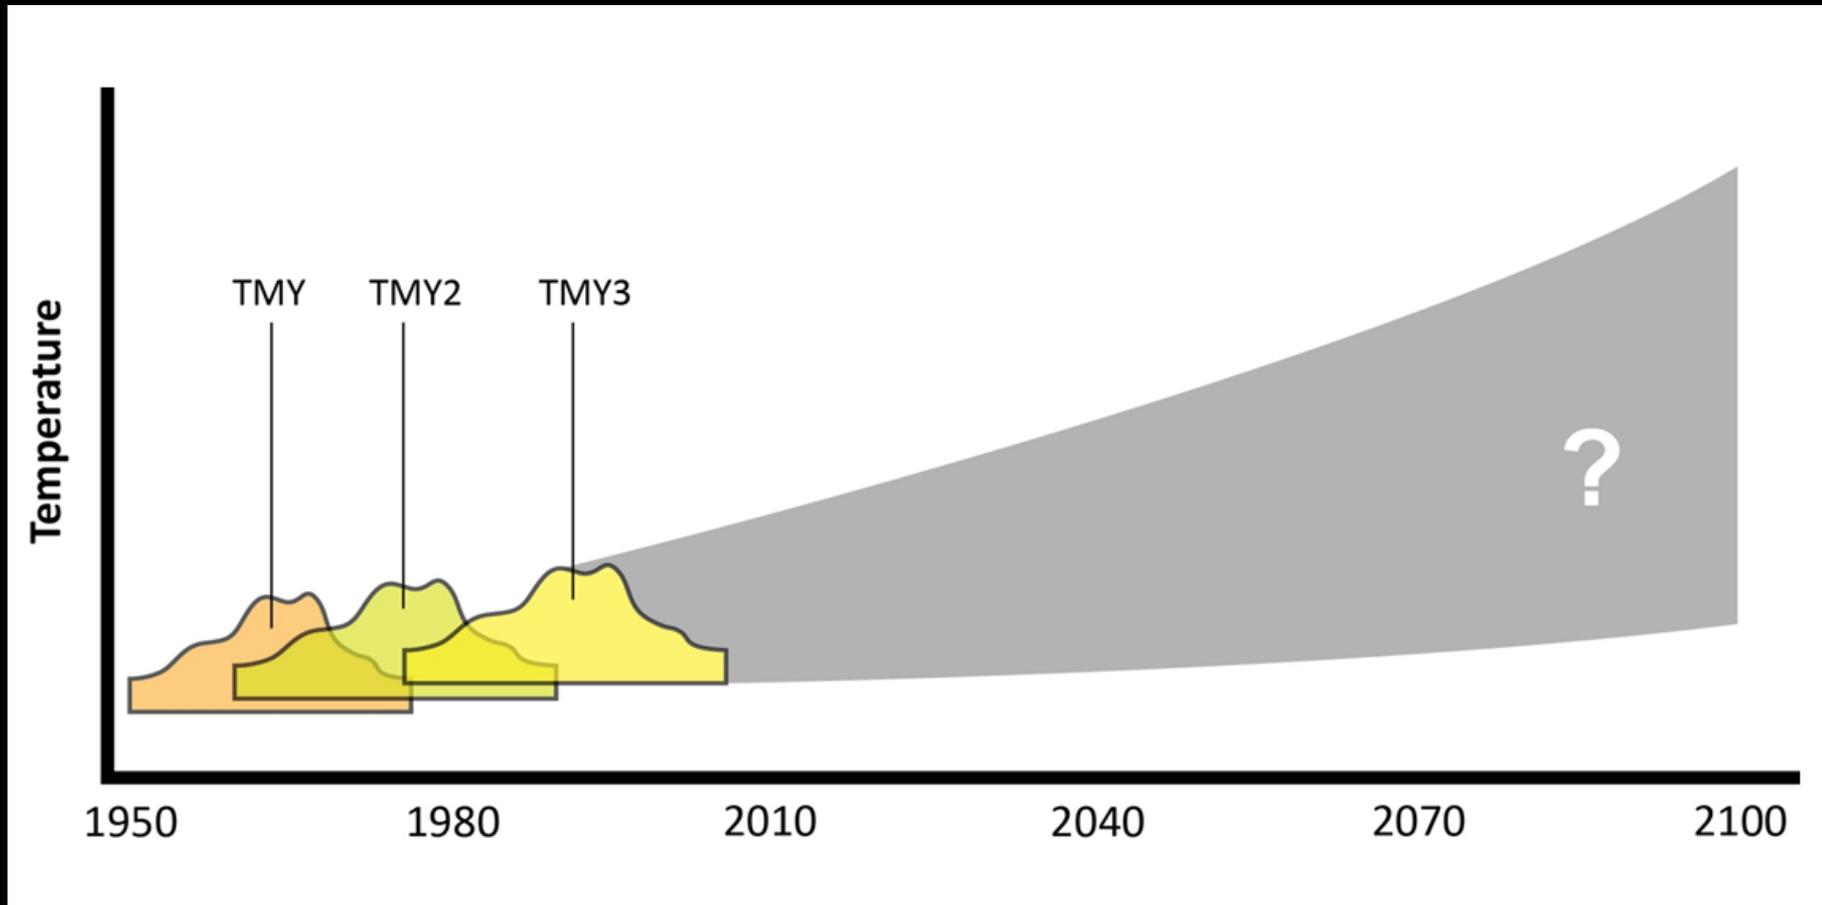

Relative Humidity [%]

Direct & Diffuse Solar Radiation [W/m^2]

Wind Speed & Direction [km/h]

- Note:**
- Many simulations find TMY not stringent enough to meaningfully test the performance of a building under extreme weather conditions such as heat waves.
 - There is a new set of weather data for the US every 12 years. We are currently at TMY3.
 - Weather data will change due to climate change.

TMY, TMY2, TMY3,...

EnergyPlus Weather Data

Weather Data

Weather data for more than 2100 locations are now available in EnergyPlus weather format — 1042 locations in the USA, 71 locations in Canada, and more than 1000 locations in 100 other countries throughout the world. The weather data are arranged by World Meteorological Organization region and Country.

View Weather Data

Select a region below to view weather data.

Africa (WMO Region 1)
Asia (WMO Region 2)
South America (WMO Region 3)
North and Central America (WMO Region 4)
Southwest Pacific (WMO Region 5)
Europe (WMO Region 6)

Global Horizontal Radiation for Different Latitudes

Annual Solar Radiation

■ < 900 kWhm-2

■ 1200 - 1500 kWhm-2

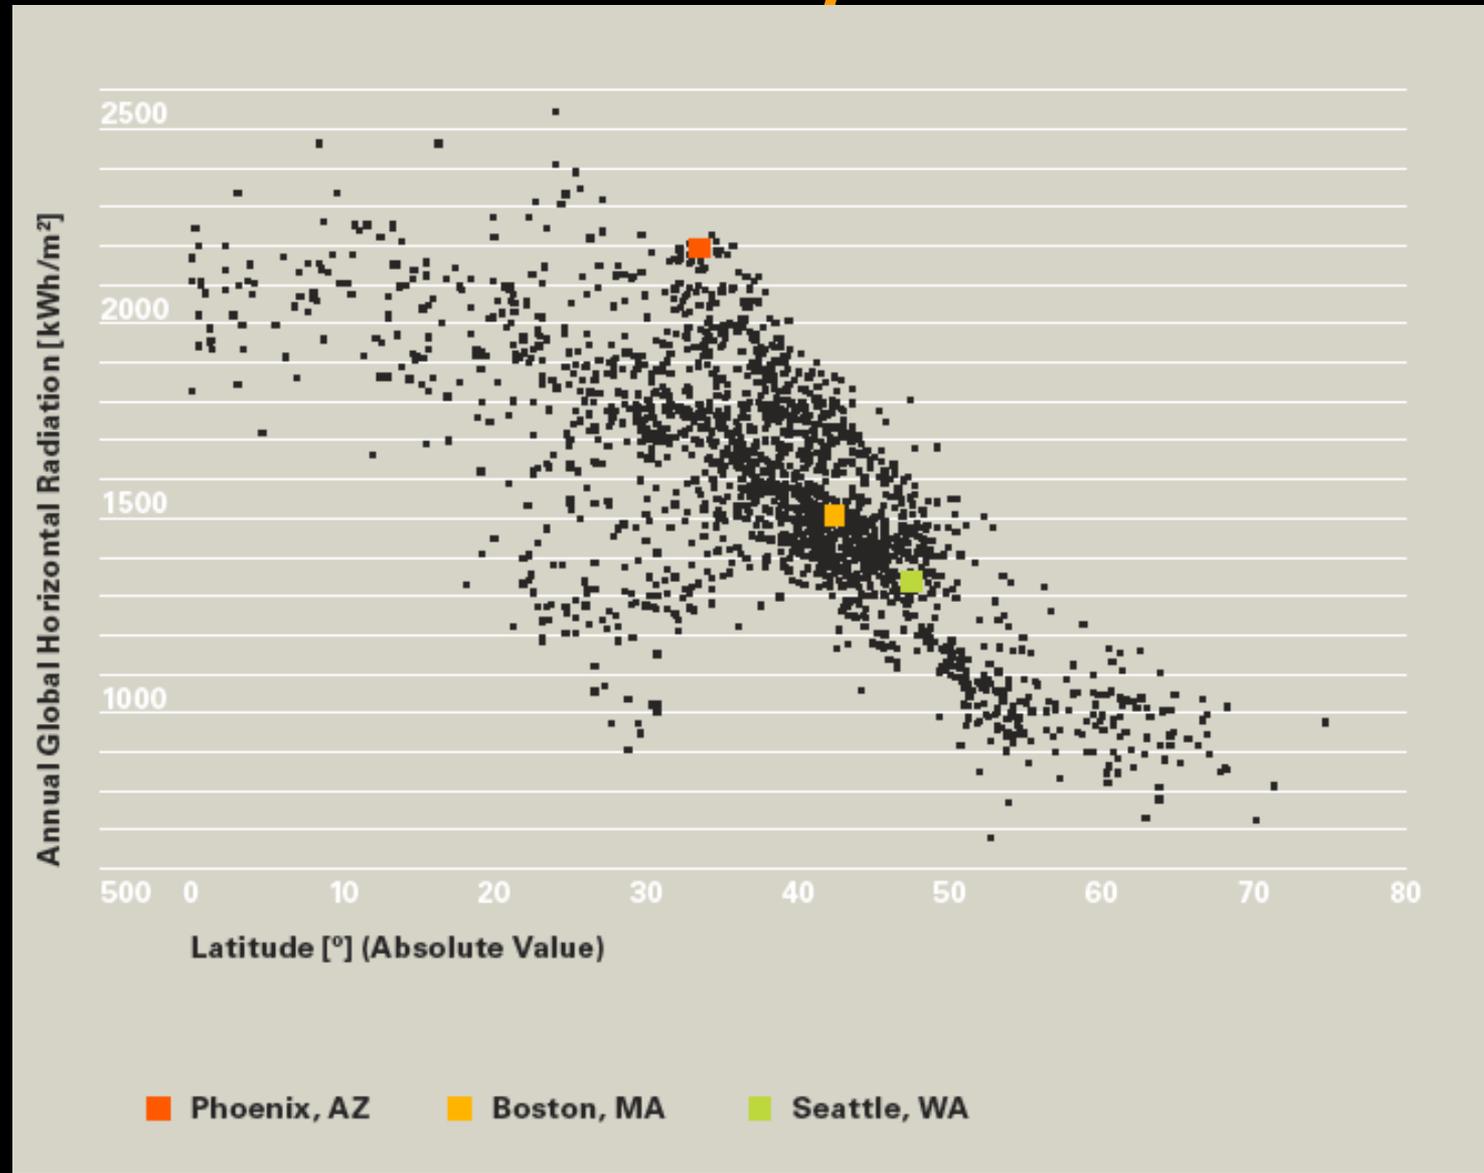

■ 1800 - 2100 kWhm-2

■ 900 - 1200 kWhm-2

■ 1500 - 1800 kWhm-2

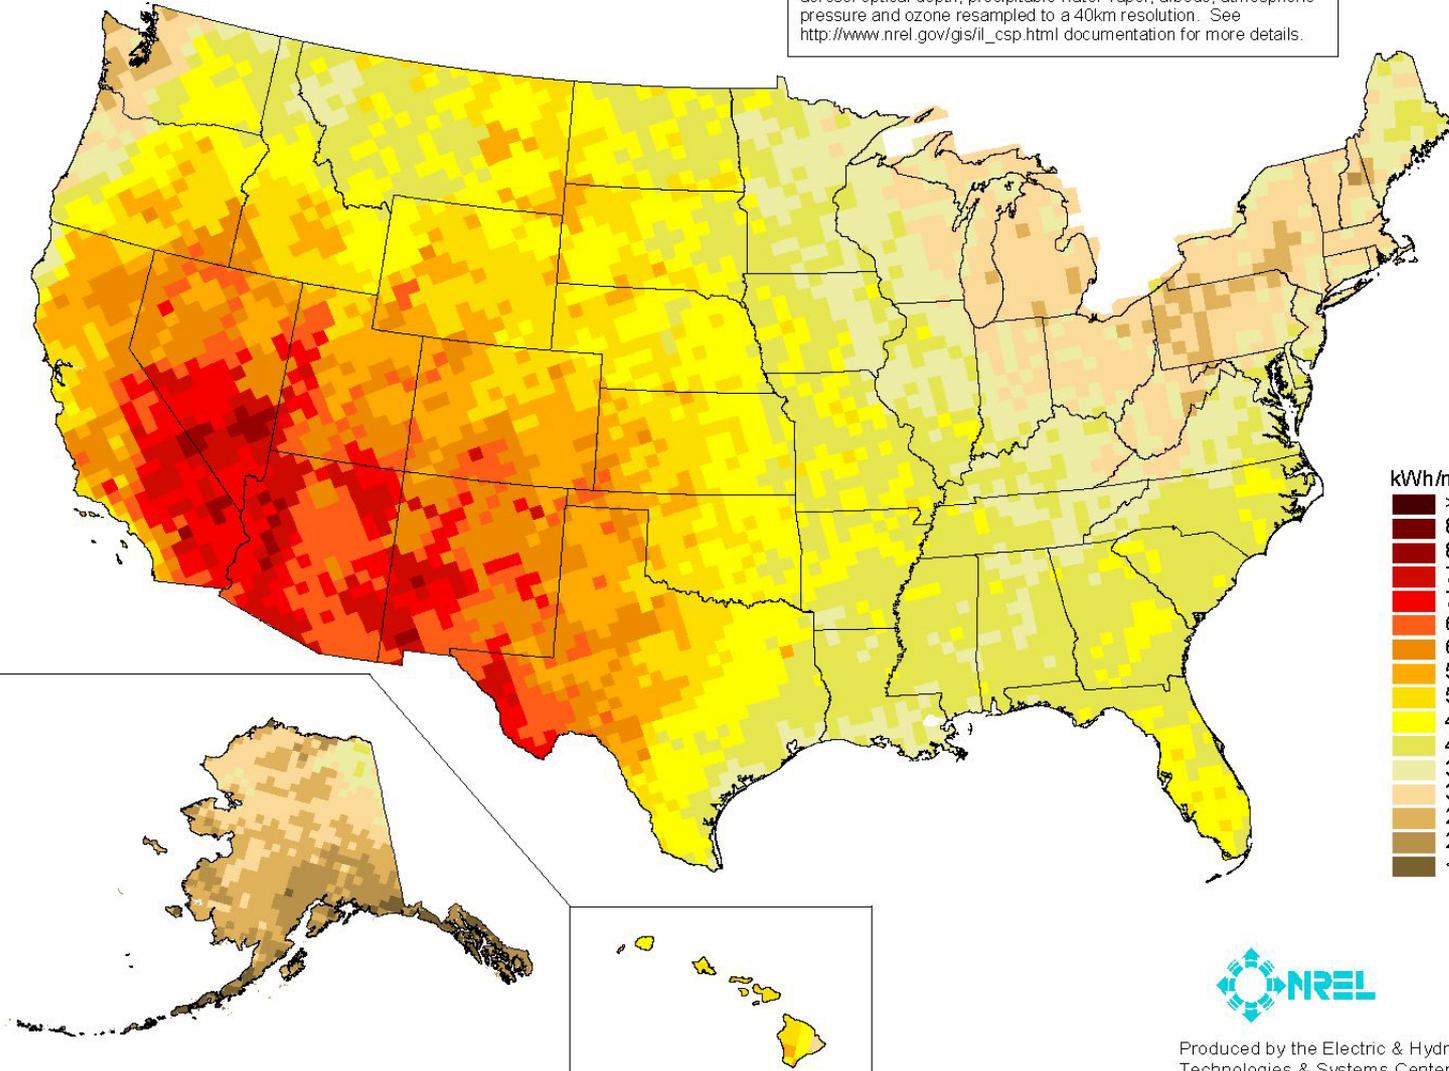

■ > 2100 kWhm-2

Annual Solar Radiation by Latitude

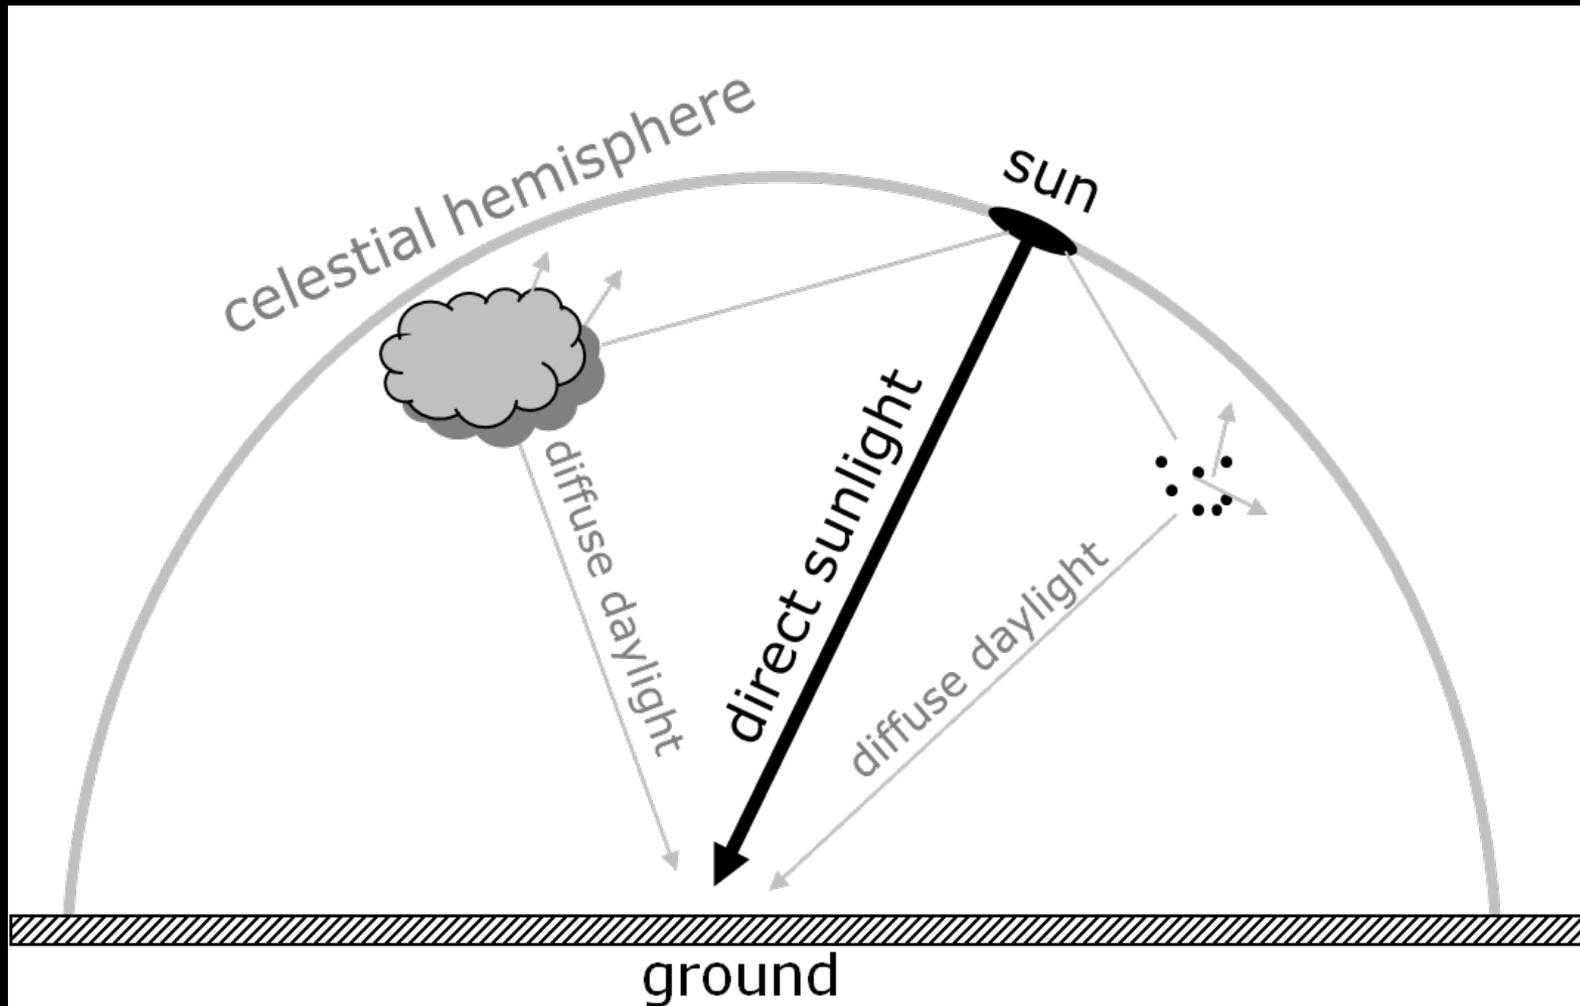

Solar Radiation throughout the US

Model estimates of monthly average daily total radiation using inputs derived from satellite and/or surface observations of cloud cover, aerosol optical depth, precipitable water vapor, albedo, atmospheric pressure and ozone resampled to a 40km resolution. See http://www.nrel.gov/gis/ii_csp.html documentation for more details.

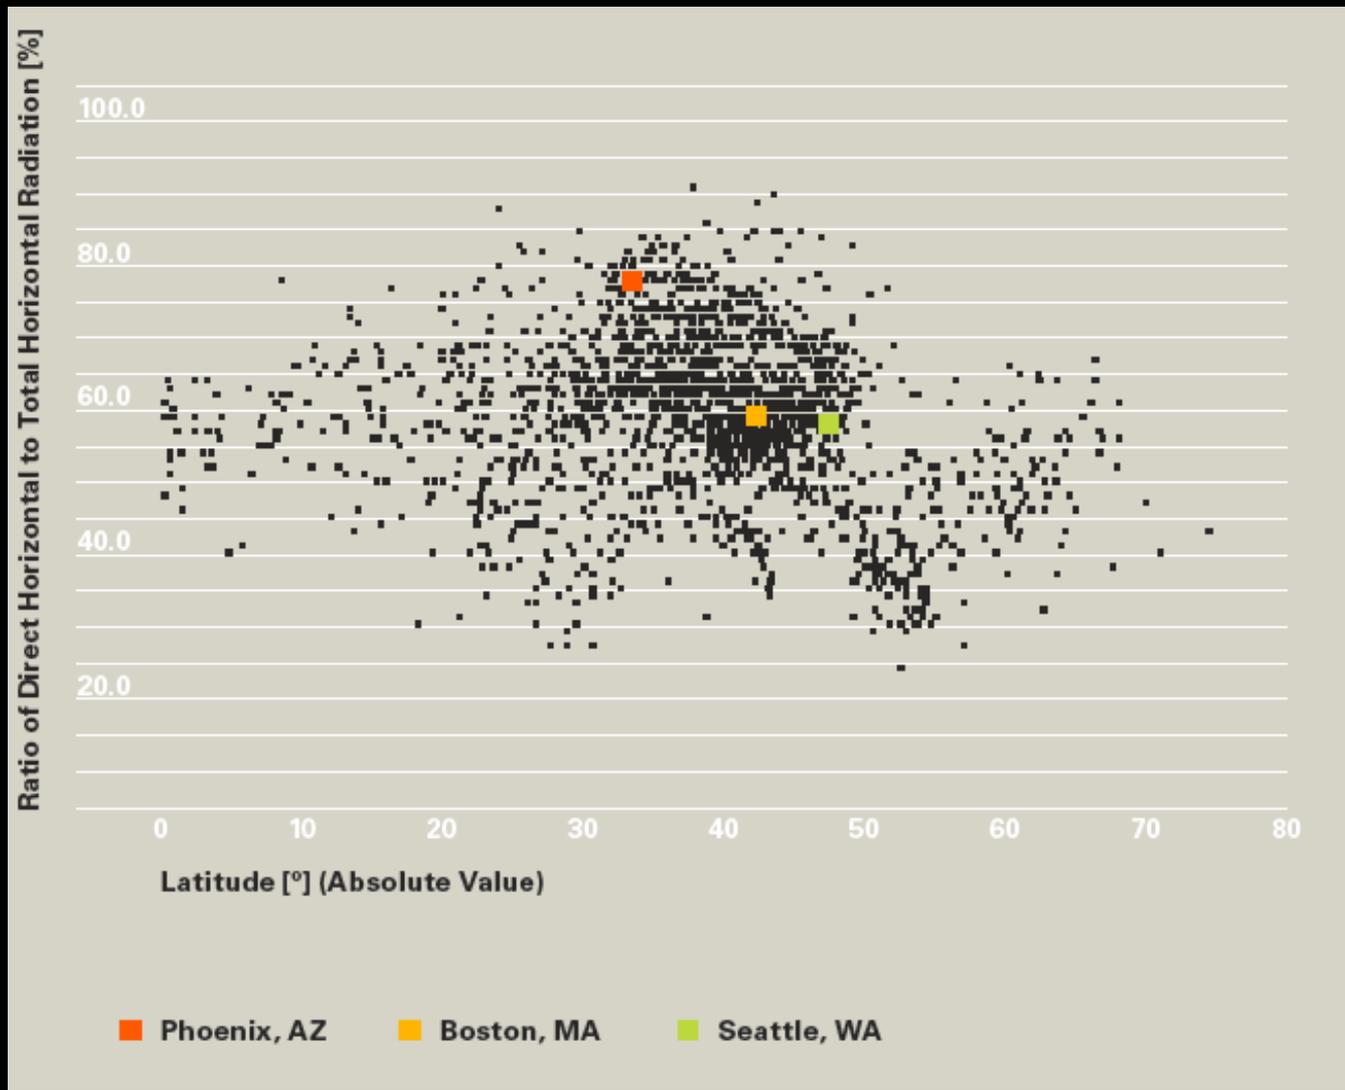

Produced by the Electric & Hydrogen Technologies & Systems Center - May 2004

Direct Sunlight and Diffuse Daylight

A considerable part of the sunlight that enters the Earth's atmosphere is scattered/reflected off clouds, aerosols, air molecules, and water vapor before it hits the Earth's surface. This part is responsible for the blue sky and is called **diffuse daylight**.

Ratio of Direct to Total Solar Radiation

- ☐ 50-70% of all solar radiation is direct.
- ☐ I.e., you always should know where the sun is.

Radiation for Different Sky Types

100-400 W/m²

600-1000 W/m²

Overcast Sky

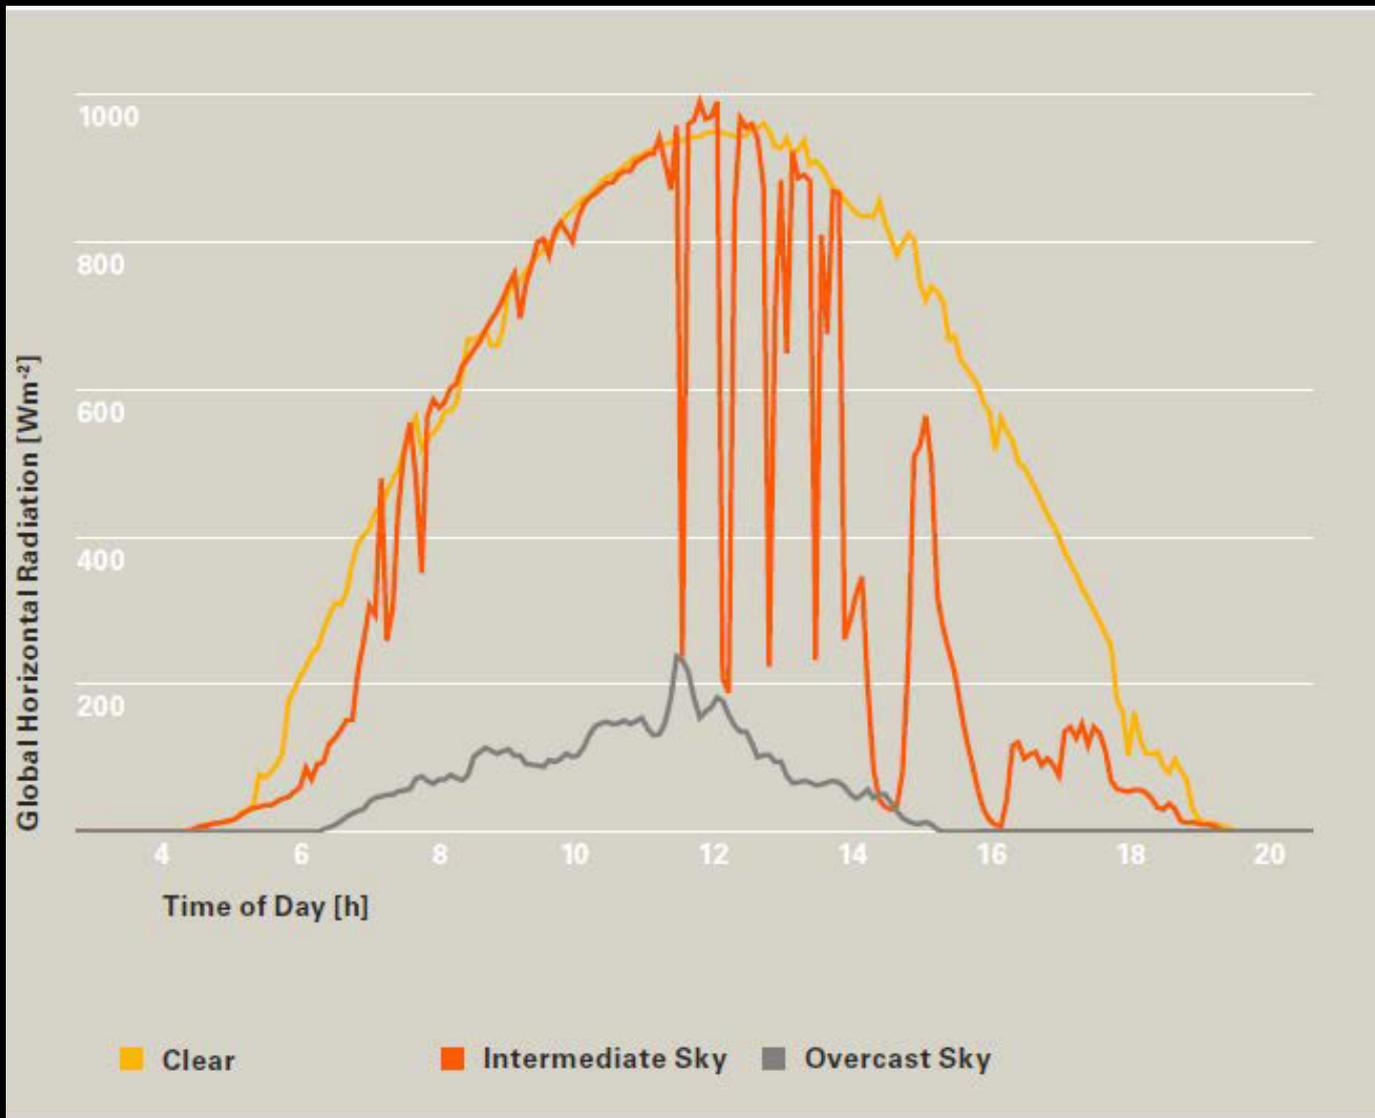

Partly Cloudy Sky

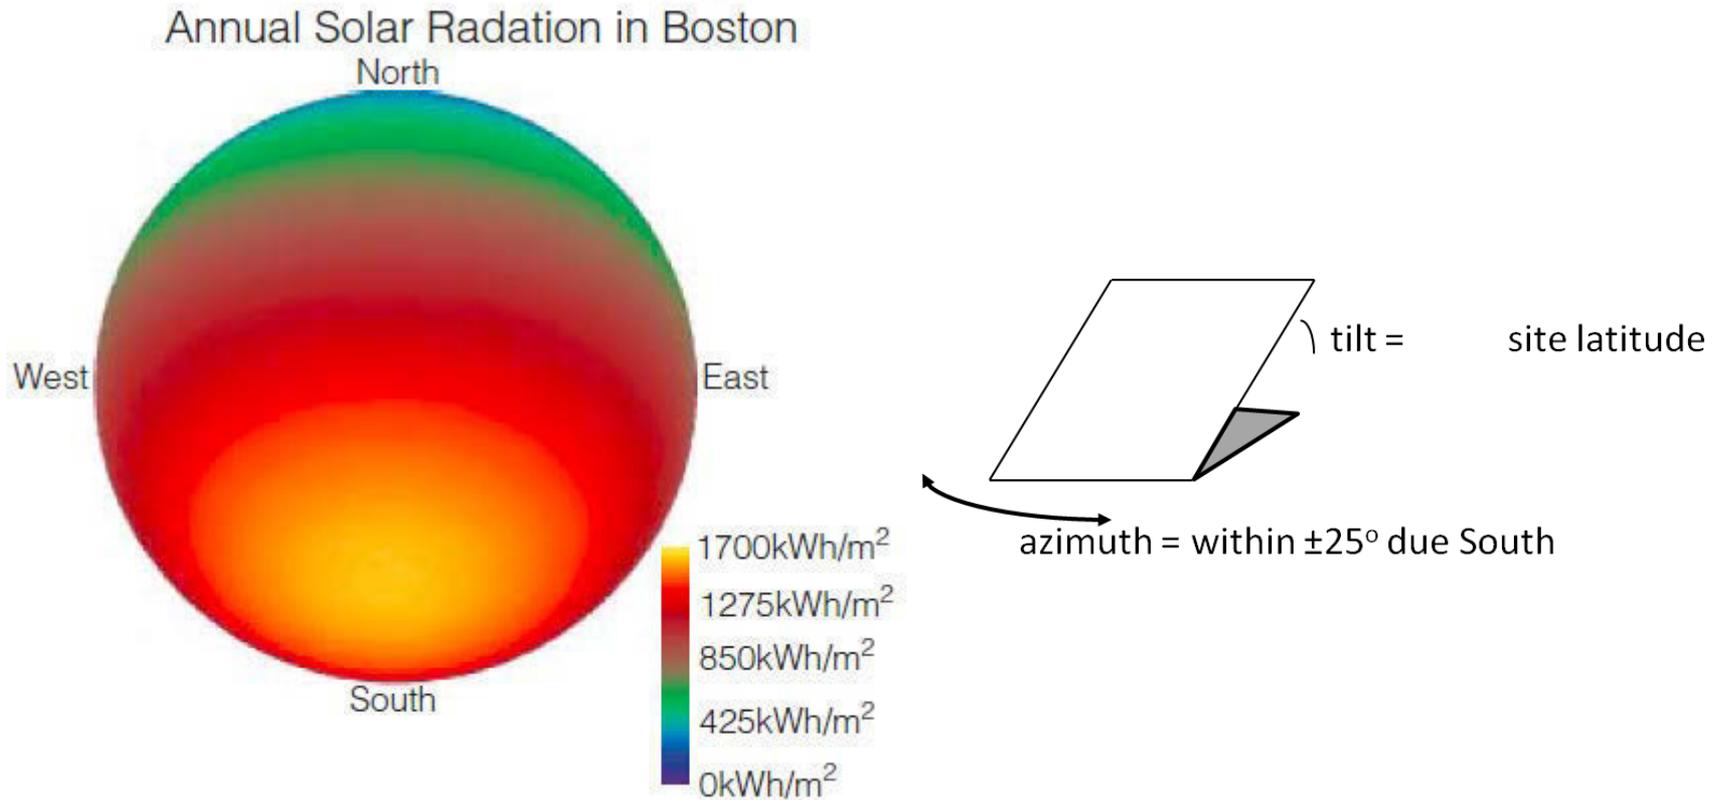

Clear Sky

Sky Conditions

Distribution of Radiation

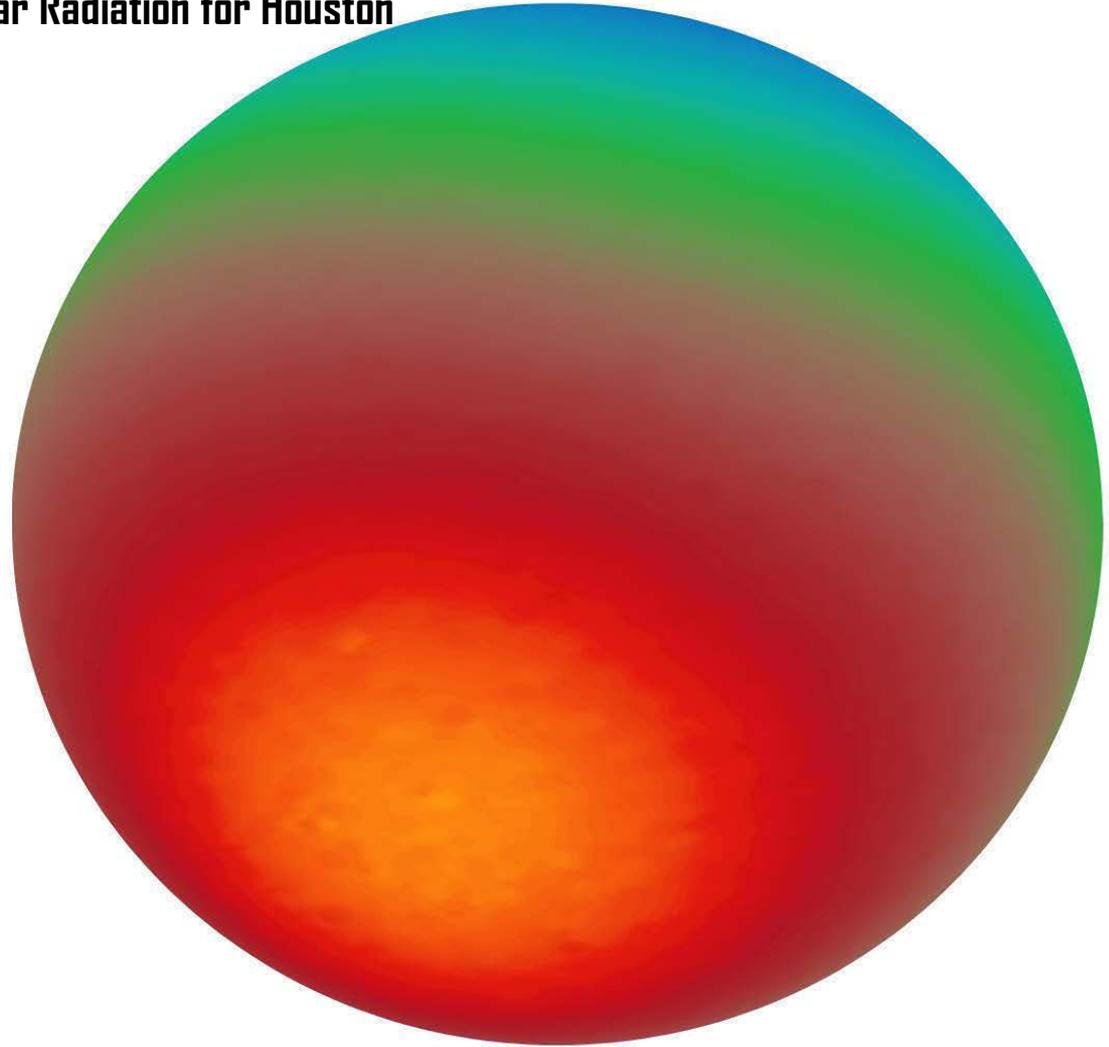

Design Principle: Rule of Thumb for Solar Radiation

The maximum annual solar radiation generally falls onto a surface with a tilt angle that corresponds to the site's latitude and that is facing within $\pm 25^\circ$ due South.

Annual Solar Radiation for Houston

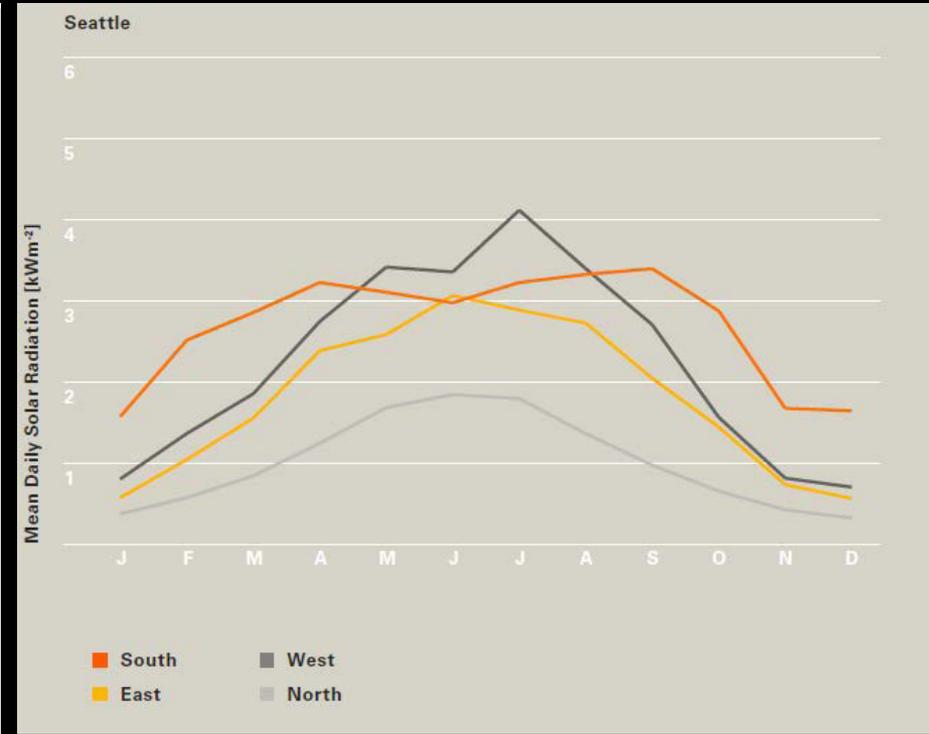

2100

Daily Radiation on Surfaces

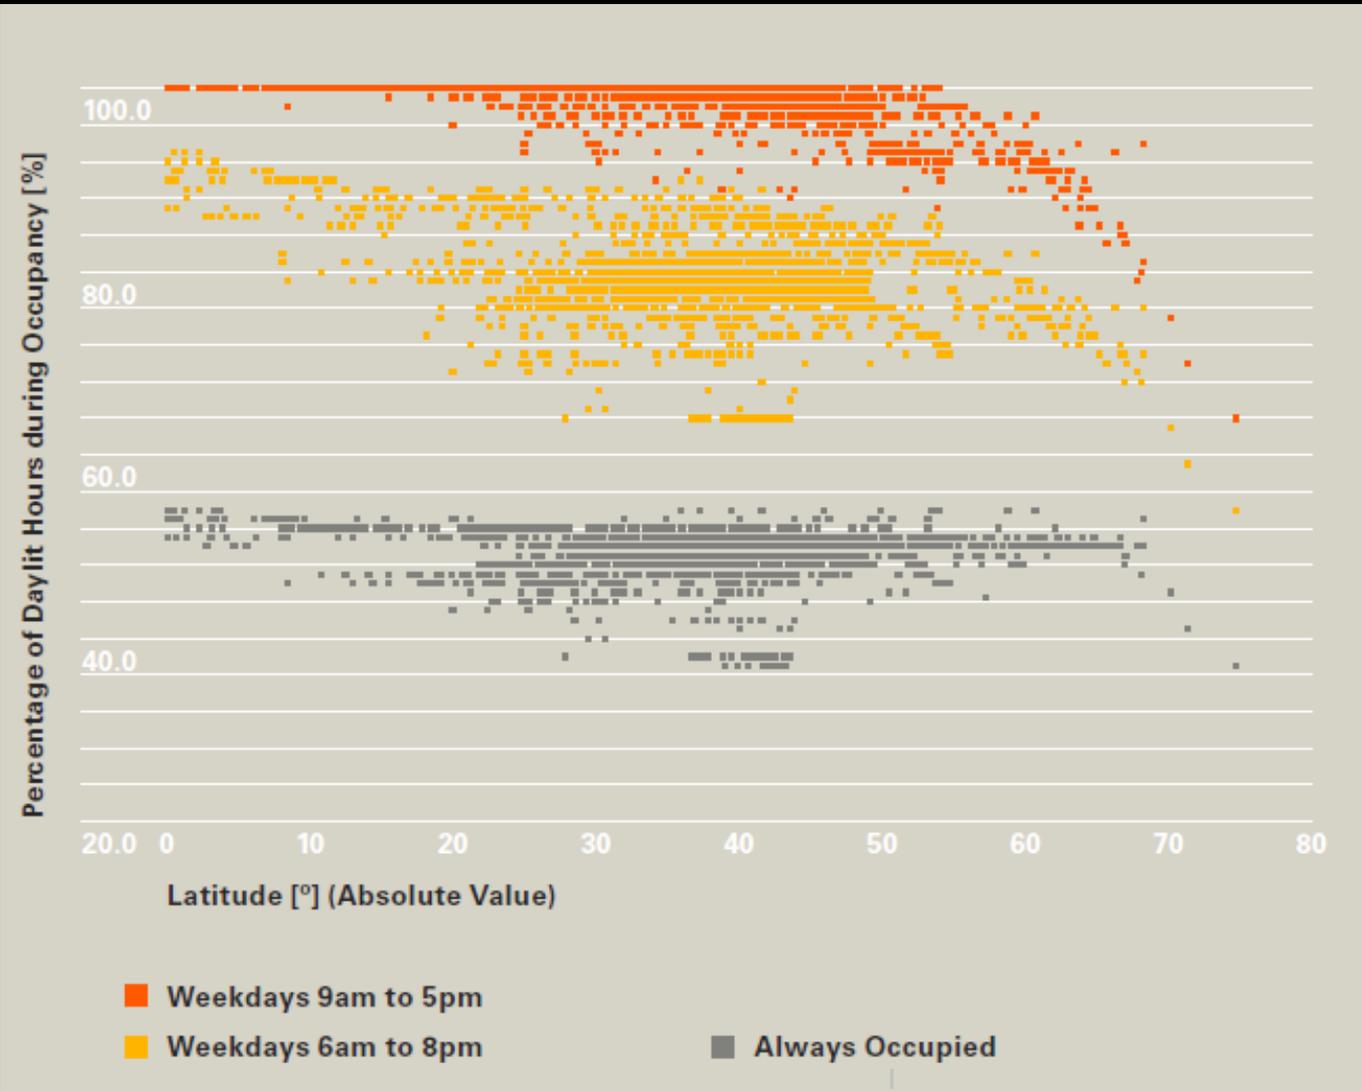

Southward orientation is less beneficial in Seattle than in Arizona.

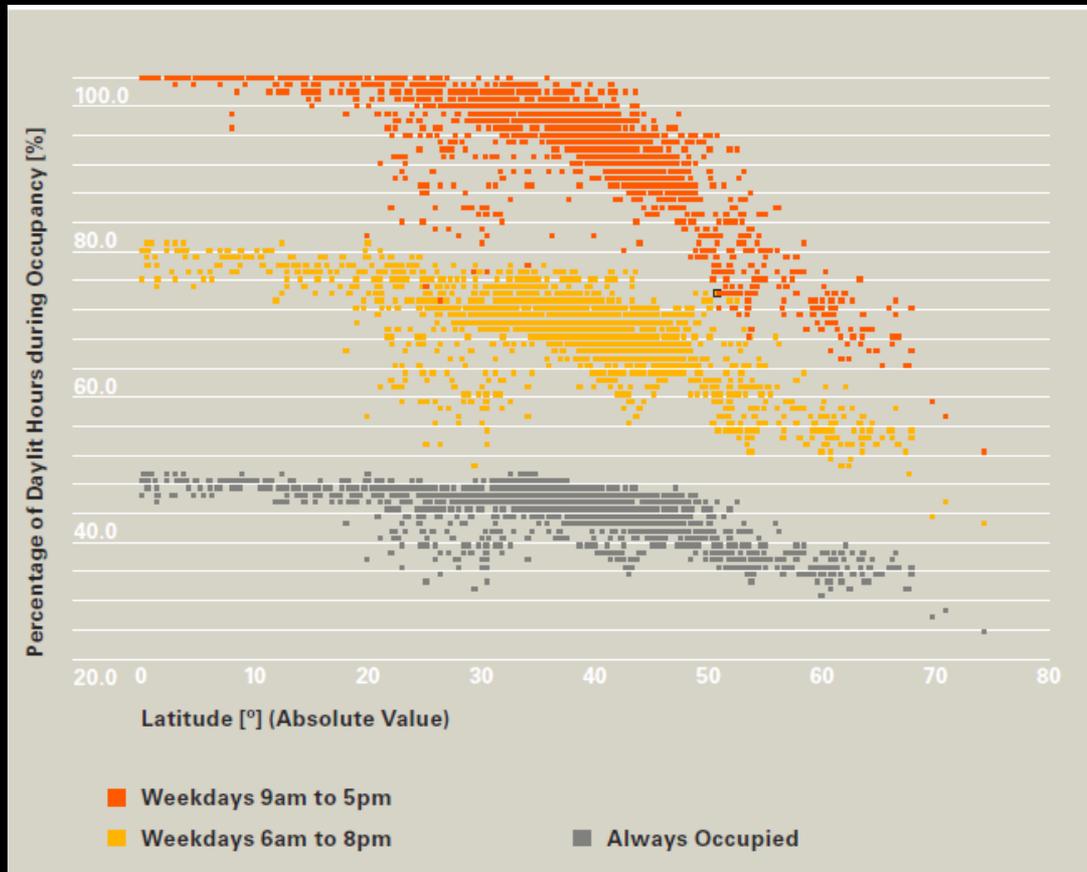

Daily Radiation for Boston

Percentage of Outside Daylit Hours During Occupancy

Percentage of Inside Daylit Hours During Occupancy

□ For latitudes below 50° there is also the potential to daylight interior spaces for 80% of core commercial hours. With 93% of the world's population living at latitudes below 50°, daylighting can be considered to be a **global solution for lighting buildings**.

Where is the sun?

Analemma over MIT

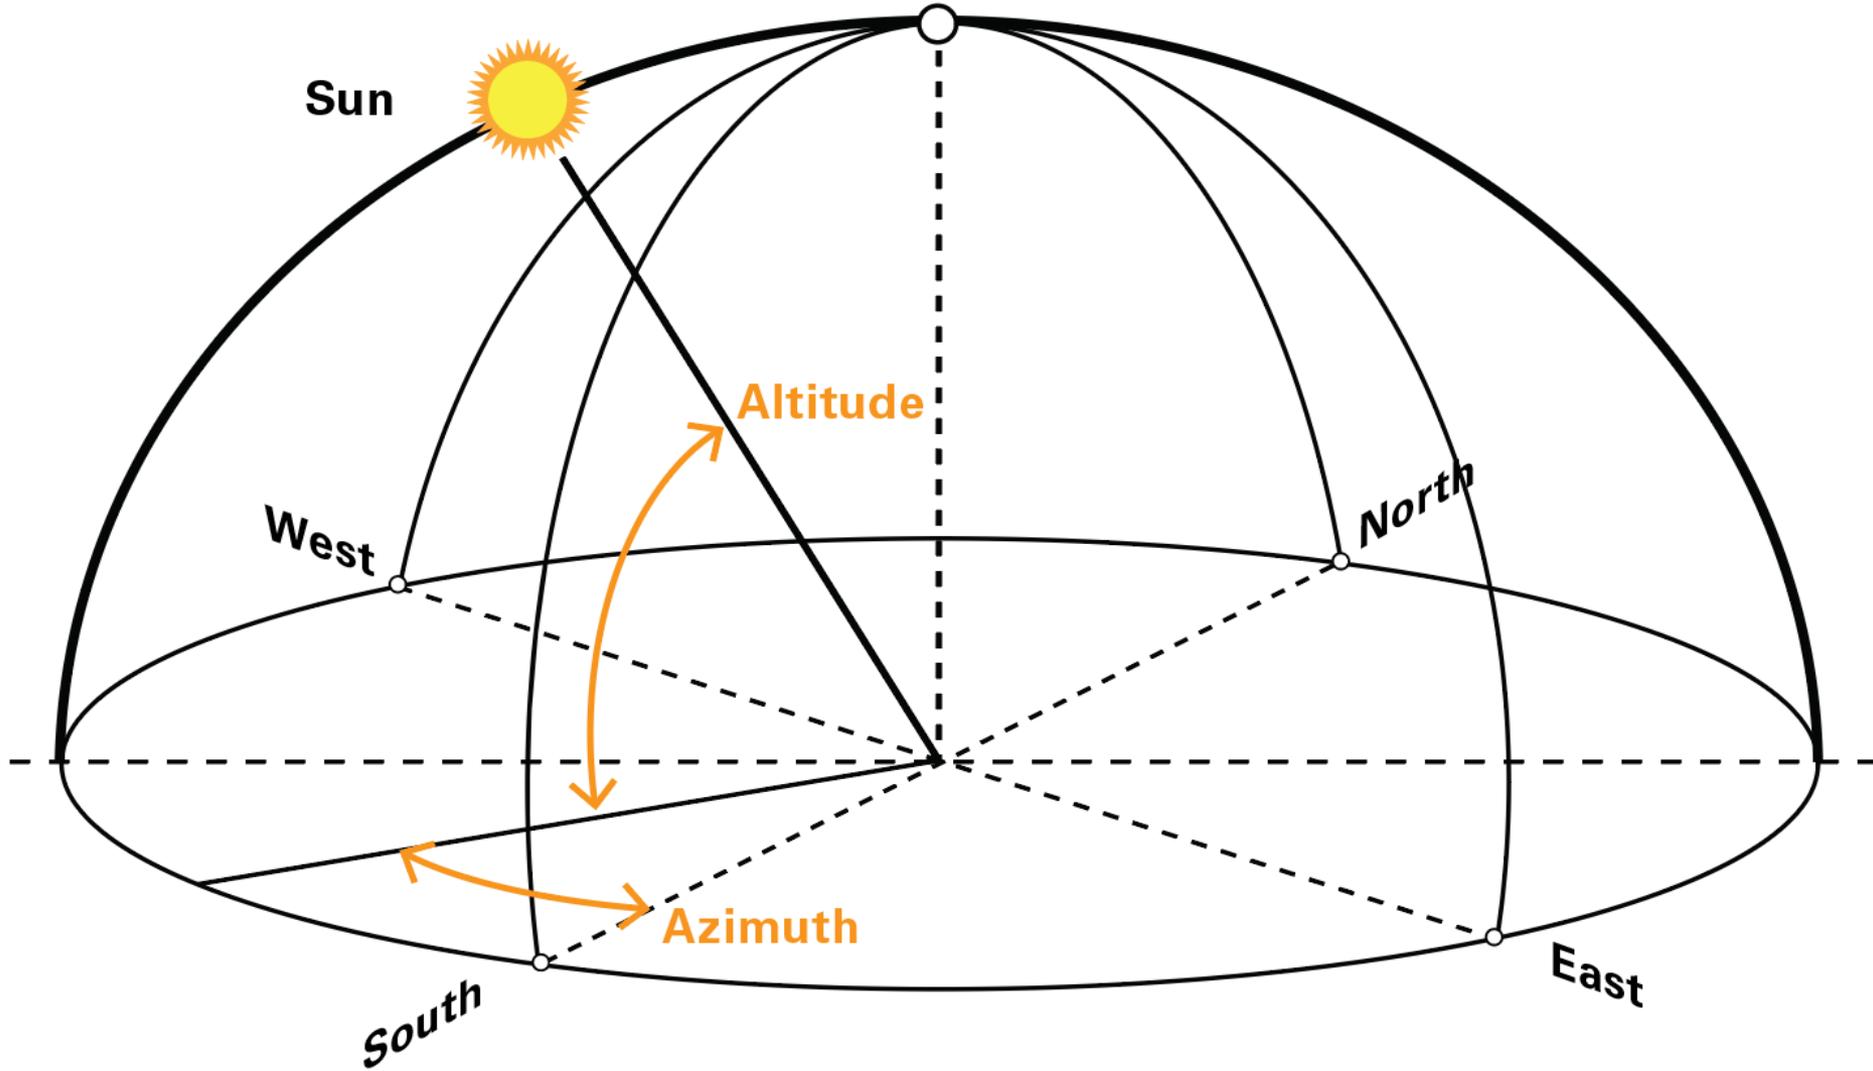

Earth's Orbit around the Sun

□ Elliptical path; declination = 23.45°

Local Solar Coordinate System

What time is it?

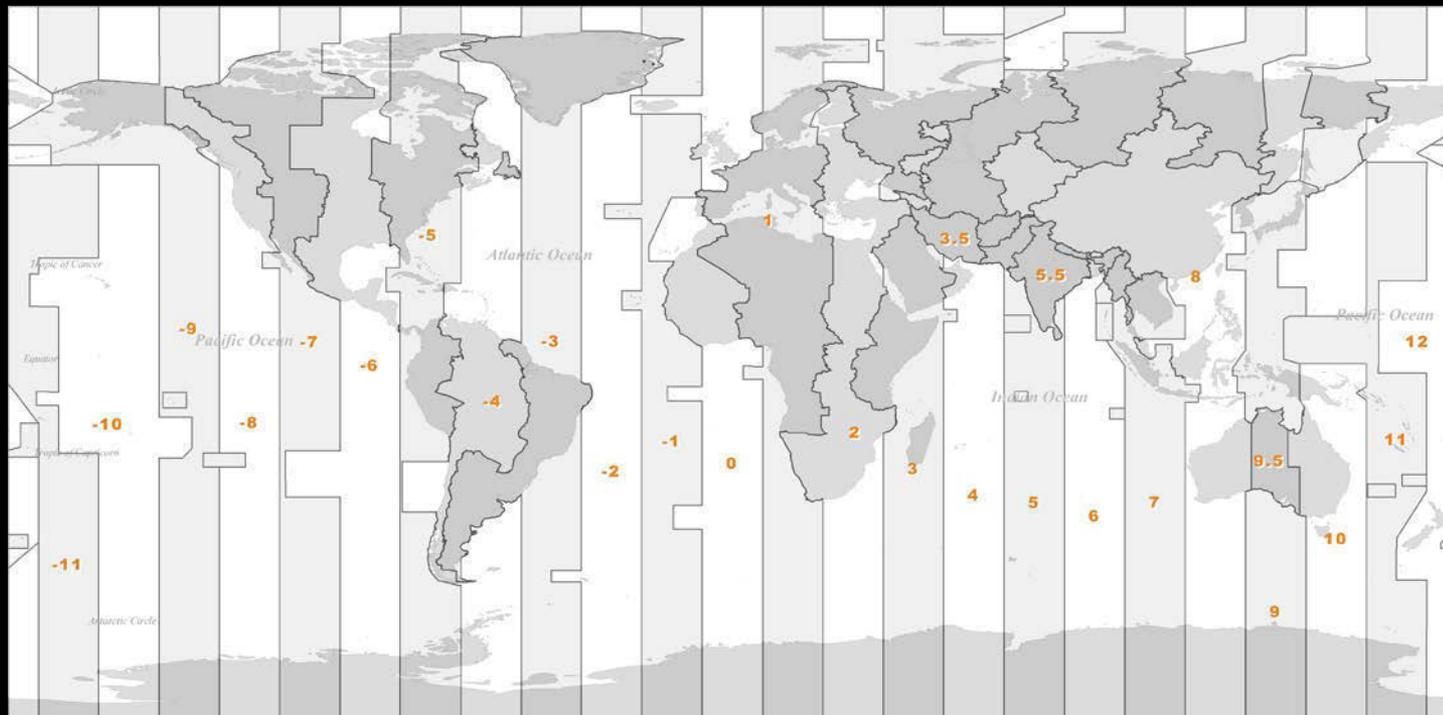

In our daily life we commonly refer to our location's **standard local time**.

☐ Standard times are synchronized with the times of all other locations within the same **time zone**.

☐ Greenwich Mean Time (GMT) is the local time at Greenwich, England.

☐ In Boston we are five time zones west of Greenwich (GMT-5).

☐ Time zones divide the earth into 24 strips that are each about **15° wide** even though time zones also follow political and geographic boundaries.

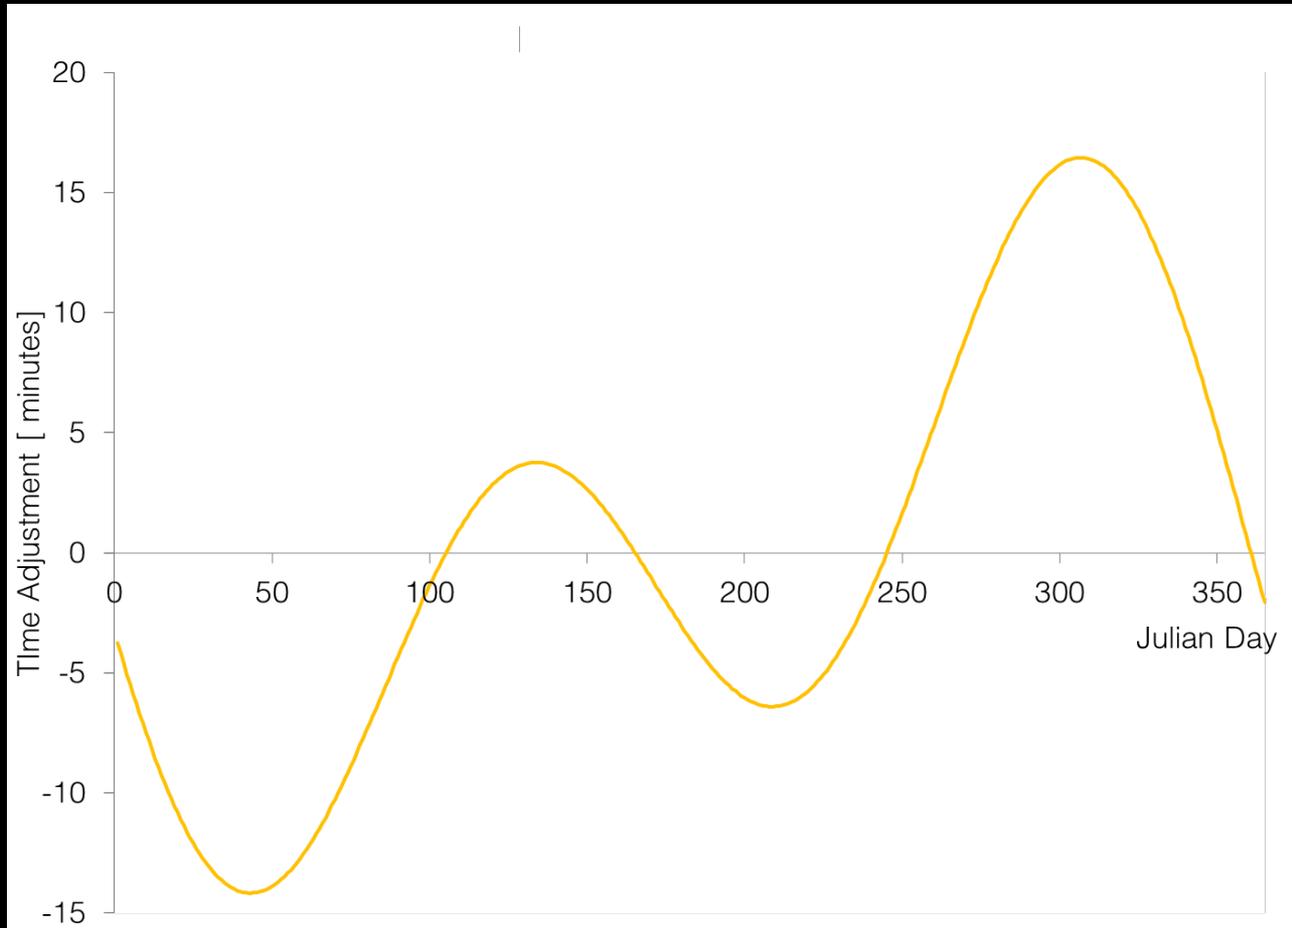

Why a standard time?

- ❑ The introduction of a standard time facilitates long distance travel and communication.
- ❑ A disadvantage of using standard time is that our experience of time is not directly linked to the position of the sun any more.
- ❑ Before the introduction of standard time in the US in 1883, different versions of solar time were used instead.
- ❑ In true solar time it is noon exactly when the sun is located to the south (azimuth angle equals zero).
- ❑ Solar time Boston is about 11 minutes ahead of solar time New York since both cities have different longitudes.

Equation of Time

□ A second difference between standard time and solar time is caused by the elliptical movements between sun and earth. This time difference is called the 'equation of time'.

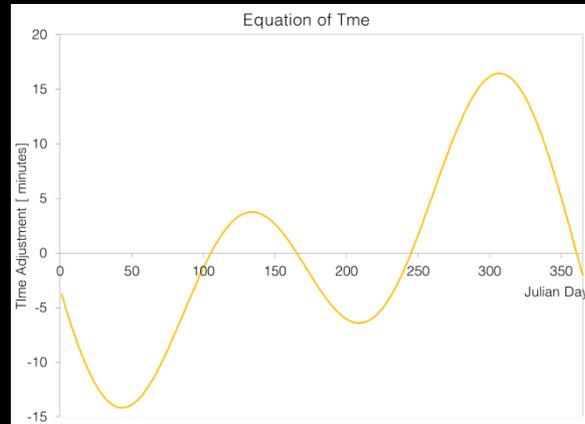

From Local to Solar Time

$$\begin{aligned} \text{Solar Time} &= \text{Standard Local Time} \\ &+ 4 \times (\text{Longitude}_{\text{standard}} - \text{Longitude}_{\text{observer}}) \\ &+ \text{equation of time} \end{aligned}$$

Standard Local Time

Equation of Time

Example

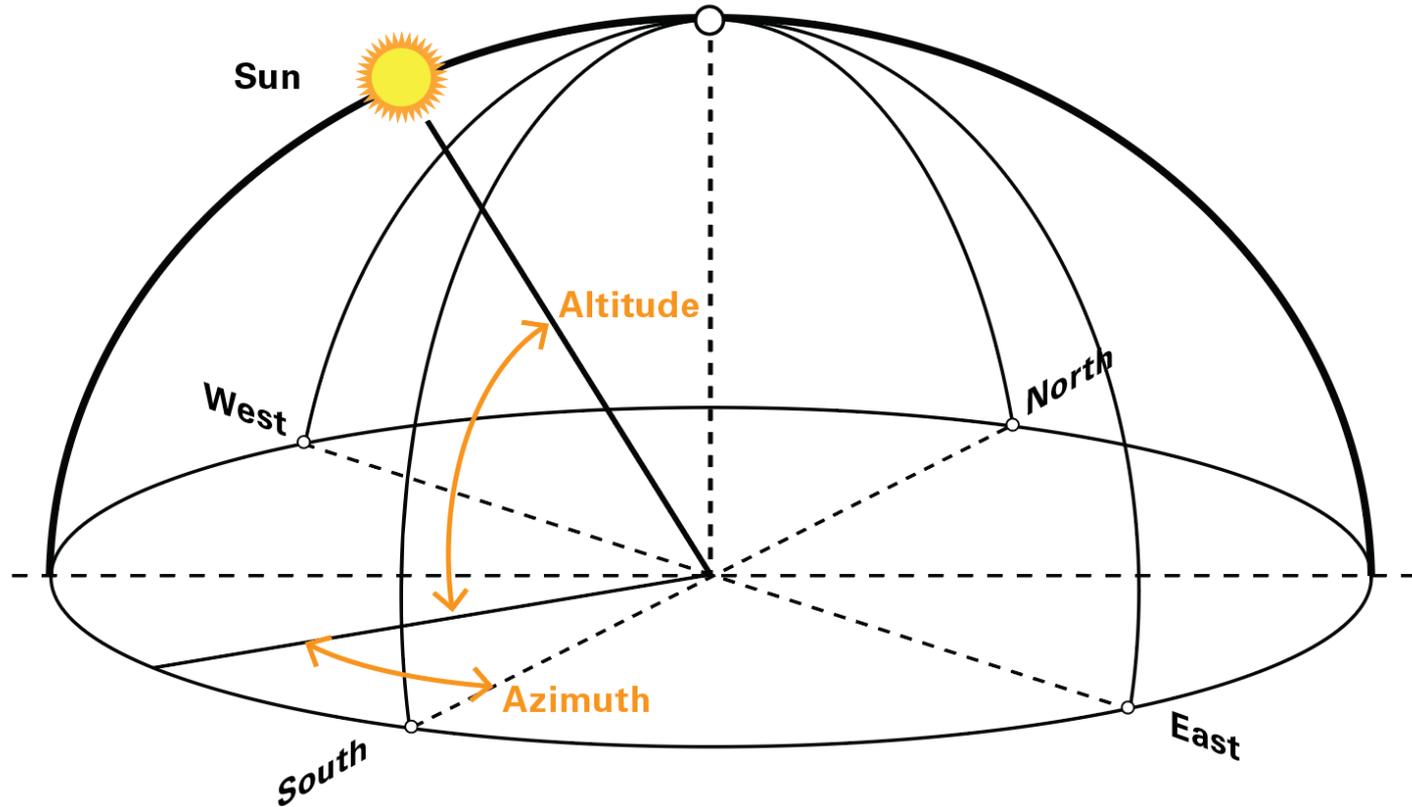

Standard Time = Feb 29 2012 at 10.04 AM in Boston

$$4 \times (\text{Longitude}_{\text{standard}} - \text{Longitude}_{\text{observer}}) = 4 \times (75^\circ \text{W} - 71.02^\circ \text{W}) = 15.9 \text{ min}$$

$$\text{equation of time (Feb 29)} = -12.5 \text{ min}$$

$$\text{Solar Time} = 10 \text{ h } 4 \text{ min } -12.54 + 15.92 \text{ min} = 10 \text{ h } 7.4 \text{ min} = 10.12333$$

Sun Position

$$\text{Azimuth} = \tan^{-1} \left(\frac{\cos(d)\sin(ST/24)}{-\cos(\text{Lat})\sin(d) - \sin(\text{Lat})\cos(d)\cos(ST/24)} \right) \quad \text{Equ 6-3}$$

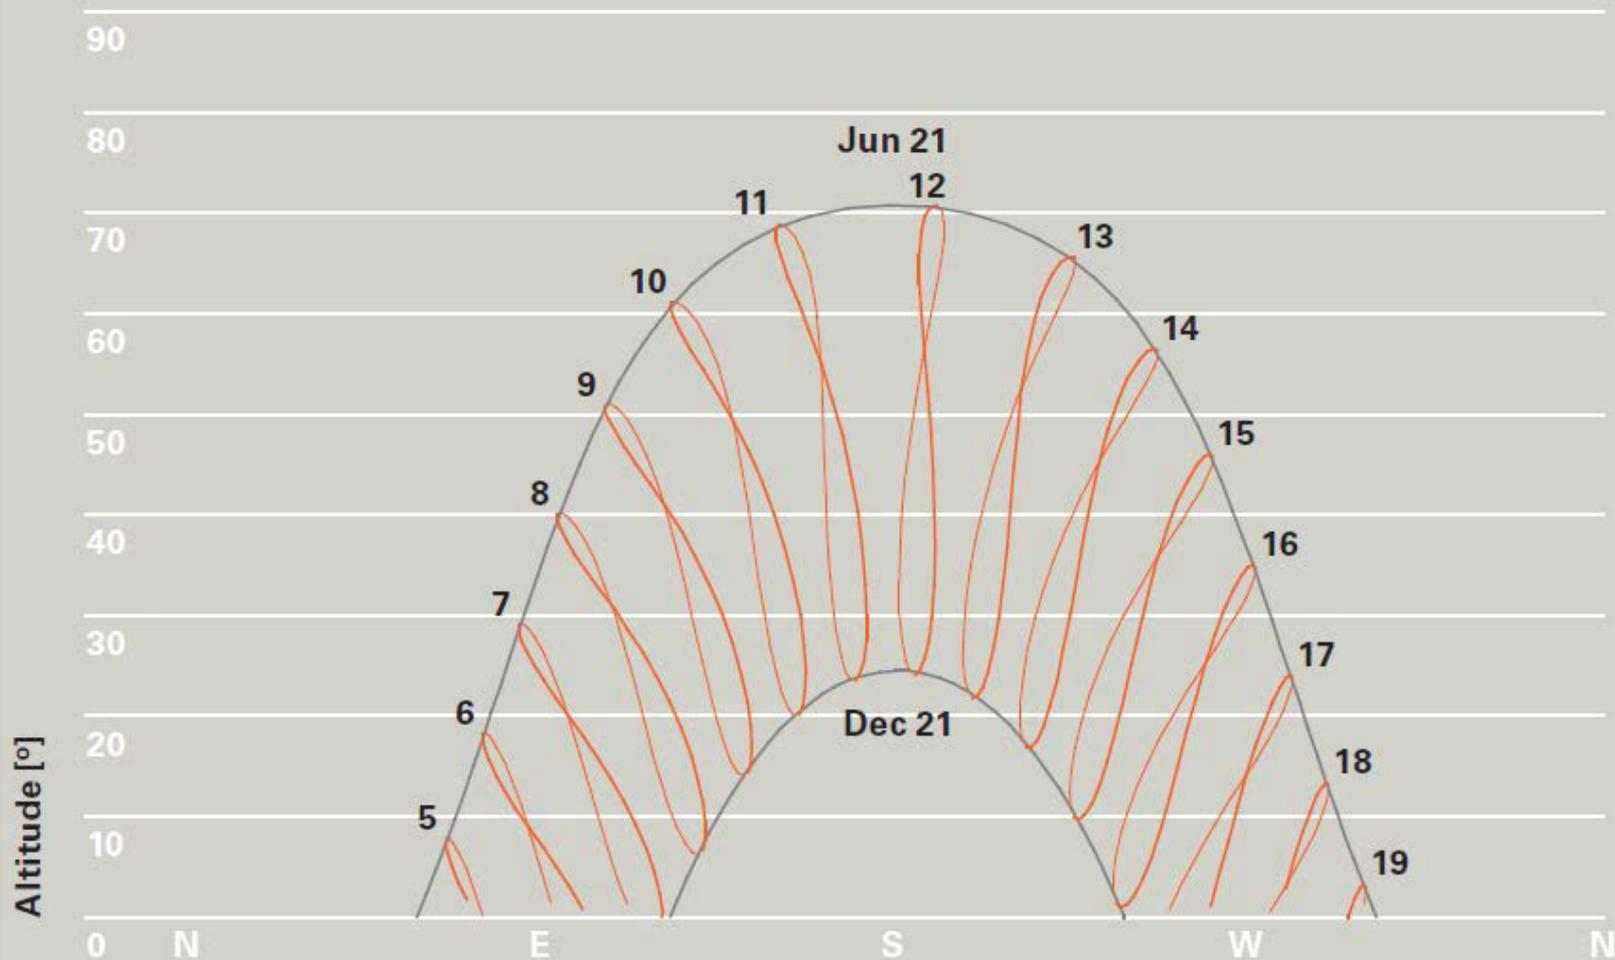

$$\text{Altitude} = \sin^{-1} \left(\sin(\text{Lat})\sin(d) - \cos(\text{Lat})\cos(d)\cos(ST/24) \right) \quad \text{Equ 6-4}$$

where d = declination = 23.45° ; ST = solar time in decimal hours; Lat = site's latitude in degrees.

Sun Path Diagram

43

Excel Spreadsheet: http://mit.edu/sustainabledesignlab/teaching_resources.html >> Climate File Analyzer

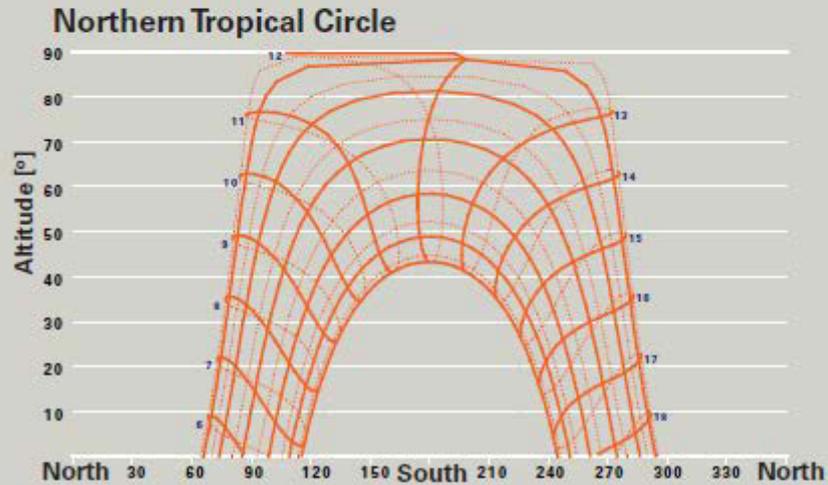

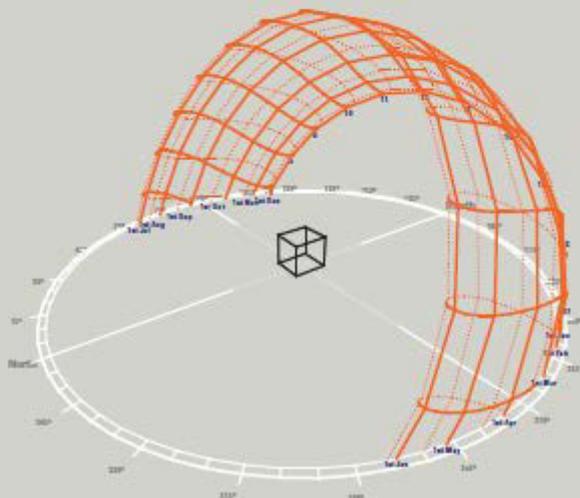

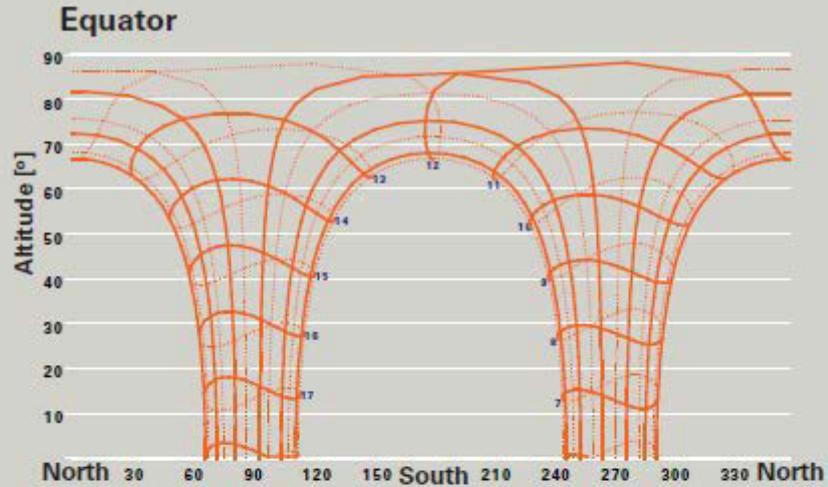

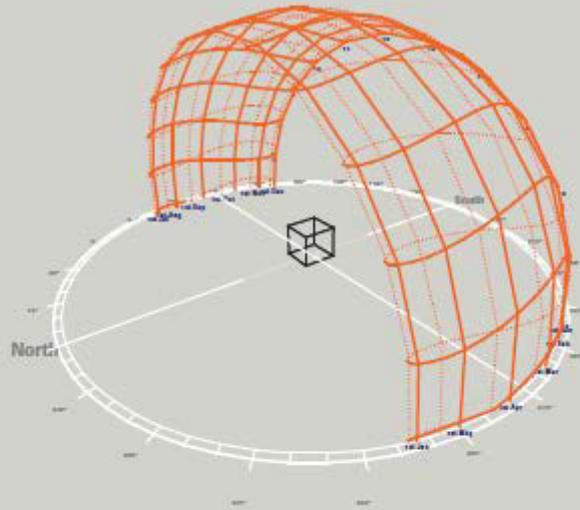

- ☐ Solar altitude range at noon = $90^\circ - \text{latitude} \pm 23.45^\circ$
- ☐ Example Cambridge (42.4°N): $90^\circ - 42.4^\circ \pm 23.45^\circ$ 24° to 70°

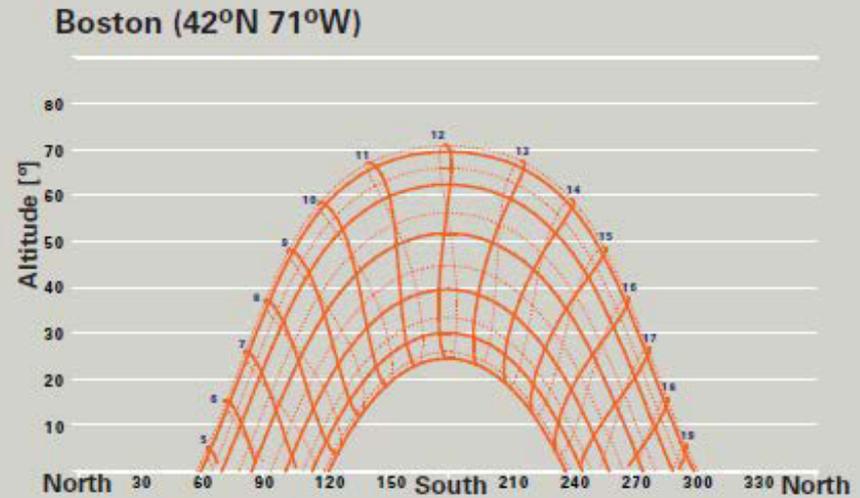

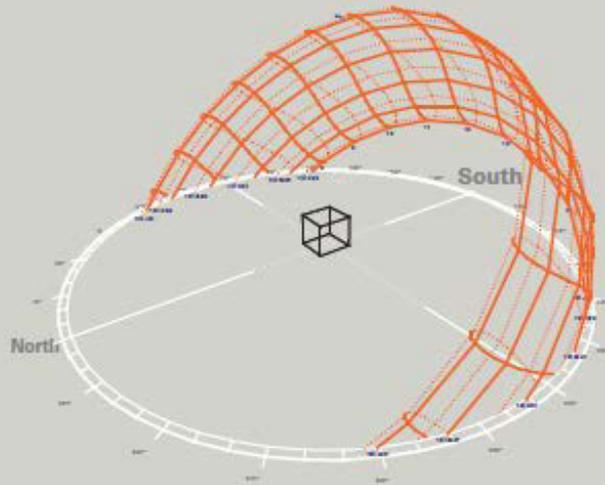

Sun Chart Examples in DIVA 4

- ❑ *Local time vs. solar time (Boston, New York City)*
- ❑ *Move from equator to pole*
- ❑ *Southern vs. Northern hemisphere*
- ❑ *Solar altitude range at noon = $90^\circ - \text{latitude} \pm 23.45^\circ$*
- ❑ *Example Cambridge (42.4°N): $90^\circ - 42.4^\circ \pm 23.45^\circ$
 24° to 70°*
